Zoltán Vas, Hungarian Natural History Museum, Department of Zoology, Hymenoptera Collection, H-1088 Budapest, Baross u. 13., Hungary. E-mail: vas.zoltan@nhmus.hu

Abstract. Five new species of *Venturia* Schrottky, 1902 are described from the Afrotropical and Oriental regions, *Venturia aurantia* sp. nov. from South Africa, *Venturia erythrina* sp. nov. from Tanzania, *Venturia ignea* sp. nov. from Ghana, *Venturia veruta* sp. nov. from Uganda, and *Venturia biroi* sp. nov. from India. The hitherto unknown male sex of *Venturia peringueyi* (Cameron, 1906), a South African species, is also described. Additionally, the first records of *Venturia aquila* Vas, 2019 and *Venturia crassicaput* (Morley, 1926) from South Africa, and *Venturia canescens* (Gravenhorst, 1829) from Cyprus, Crete and Tanzania are given.

Keywords. ichneumon wasp, species description, distribution, Old World.

INTRODUCTION

*Venturia* Schrottky, 1902 is a species-rich genus of family Ichneumonidae, subfamily Campopleginae. Prior to this study 138 valid species were known worldwide; 44 of them occur in the Neotropical, 40 in the Nearctic, 35 in the Oriental, 11 in the Afrotropical, 8 in the Western Palaearctic, 4 in the Eastern Palaearctic, 4 in the Australasian, and 4 in the Oceanic regions (Yu et al. 2012, Vas 2019a, b).

In this paper, based on the material of the Hungarian Natural History Museum (HNHM, Budapest) and the Biological Museum of Lund University (MZLU, Lund), five new species of the genus are described (four species from the Afrotropical region and one species from the Oriental region), the hitherto unknown male sex of *Venturia peringueyi* (Cameron, 1906), a South African species, is also described, and new distributional records of some *Venturia* species are given.

MATERIAL AND METHODS

Taxonomy and nomenclature follow Yu & Horstmann (1997) and Yu et al. (2012); hence, complete nomenclatural history and list of synonymy taxa are not repeated here. The morphological terminology is primarily based on Gauld (1991) and Gauld et al. (1997); however, in some cases, especially regarding wing veins, the corresponding terminology of Townes (1969) is also indicated. In the case of Oriental species, for better comparability with Gupta & Maheshwary (1977), both the length of ovipositor sheath and the total length of exposed ovipositor are given. The identifications were based on Gravenhorst (1829), Förster (1869), Magretti (1884), Schrottky (1902), Cameron (1906, 1912), Enderlein (1914), Morley (1926), Seyrig (1935), Townes et al. (1961), Momoi (1965), Townes (1970), Horstmann (1973), Townes & Townes (1973), Gupta & Maheshwary (1977), Horstmann (1979), Wahl (1987), Kusigemati (1988), Polaszek et al. (1994), Zwart (1998), Jonathan (1999), Sudheer & Nar-
endran (2006), Horstmann (2008), van Noort (2019), Vas (2019a, b), and on checking the relevant type material (i.e. type specimens of all species listed in the taxonomy section were examined at least by digital images except that of Venturia canescens (Gravenhorst, 1829) which type material was unnecessary to check), and specimens determined by V.K. Gupta in HNHM. The specimens were identified and examined by the author using a Nikon SMZ645 stereoscopic microscope. Results are grouped into biogeographical regions, within biogeographical regions species are listed alphabetically. Label data is given as is, with clarifying, abbreviated or missing information given in brackets. Photos were taken with a 14 MP MicroQ-U3L digital camera. Post image work was done with ToupTek ToupView v4.7 and Photoshop CS3.

**TAXONOMY AND RESULTS**

**Subfamily: Campopleginae Förster, 1869**

**Genus: Venturia Schrottky, 1902**

*Type species: Venturia argentina Schrottky; designation by Viereck (1914).*  

**AFROTROPICAL REGION**

Before this study, 11 valid species were known from the region (Yu et al. 2012, Vas 2019a). Most Afrotropical species were described several decades ago (Yu et al. 2012), except quite recently a new species, *Venturia aquila* Vas, 2019 was described from Ghana, along with the unknown female sex of *Venturia crassicaput* (Morley, 1926) (Vas 2019a). With the new species described below, the number of Afrotropical *Venturia* species increased to 15.

**Venturia aquila Vas, 2019**

*Remarks.* First records for South Africa. This species was recently described from Ghana (Vas 2019). As compared to the holotype specimen of this species, the following slight intraspecific variations were observed: tegula yellow to yellowish brown, middle legs entirely blackish to dark brown.

**Venturia aurantia sp. nov.**

(Figures 1–3)

*Material examined.* Holotype: female, S. Afr. [= South Africa], Cape Prov., Cape Peninsula, Hout Bay, Skoorsteenkop, 22.I.[19]51, leg. Brinck & Rudenbeck, Swedish South African Expedition 1950–1951, No. 157, Insect trap; specimen pinned, Id. No. MZLU-HYM 26382. – Paratypes: three females, same locality, date, collector; specimens pinned, Id. No. MZLU-HYM 26383, 26396, 26398; one female and one male, same locality, collector, 2.II.[19]51, No. 166; specimens pinned, Id. No. MZLU-HYM 26389 (male, antennae missing), 26393. – The holotype and three paratype specimens (MZLU-HYM 26383, 26389, 26393) are deposited in MZLU (Lund), two paratype specimens (MZLU-HYM 26396, 26398) are deposited in HNHM (Budapest) (HNHM-HYM 154986, 154987).

*Diagnosis.* Among the Afrotropical species of the genus, *Venturia aurantia* sp. nov. could be reliably identified by the combined presence of the following characters: gena in dorsal view 0.4–0.5× as long as eye width, moderately strongly narrowed behind eye, mesopleuron punctate on granulate background, ventral part of epicnemial carina little elevated, posterior transverse carina of mesosternum elevated, medially distinctly...
Description. Female (Figs 1–3). Body length ca 7–8 mm, fore wing length ca 5 mm.

Head. Antenna with 35–37 flagellomeres; first flagellomere long and slender, 3.5–3.9× as long as wide apically; preapical flagellomeres quadruple to slightly longer than wide. Head transverse, matt, with dense, short, greyish hairs. Ocular-ocellar distance 0.8–0.9× as long as ocellus diameter, posterior ocellar distance 1.5–1.7× as long as ocellus diameter, posterior ocellar distance 1.6–1.8× as long as ocellar-ocellar distance. Inner eye orbits slightly indented, about parallel. Gena granulate with dense, superficial punctures, moderately short, in dorsal view 0.4–0.5× as long as eye width, moderately strongly narrowed behind eye. Occipital carina complete, medially evenly arched, reaching hypostomal carina little before base of mandible, hypostomal carina slightly elevated. Frons flat, without median longitudinal carina, rugose-pectinate. Face very weakly convex in profile, rugose-pectinate. Clypeus rugose-pectinate, very weakly separated from face, flat in profile, relatively wide, its apical margin very weakly convex, sharp. Malar space 0.5× as long as basal width of mandible. Mandible relatively long, lower margin of mandible with a wide flange from base toward teeth, flange gradually narrowed toward teeth, mandibular teeth of equal length.

Mesosoma. Mesosoma with dense, short, greyish hairs. Pronotum rugose-pectinate, ventral half to two-thirds with strong transverse wrinkles on predominantly smooth background; epomia strong. Mesoscutum rugose-pectinate, convex in profile, ca 1.1× as long as wide, notaular not developed. Scuto-scutellar groove wide, deep. Scutellum rugose-pectinate, convex, lateral carina indistinct. Upper half of mesepimeron densely punctate with weak rugosity, lower half densely punctate on granulate background, distances between punctures smaller than puncture diameters, with rather strong transverse wrinkles above and anterior to speculum; speculum smooth, shiny; mesepimeral suture impressed with short, relatively strong transverse costae. Epinomial carina complete, strong, pleural part bent to anterior margin of mesepimeron reaching it below its middle height, transversal part (i.e. part at the level of sternaulus running through the epinomial to the ventral edge of pronotum) not developed, ventral part (behind fore coxae) complete, little elevated. Sternaulus indistinct. Posterior transverse carina of mesosternum complete, elevated, medially distinctly excised and curved inwards, submedially convex. Metanotum rugose-pectinate, 0.4–0.5× as long as scutellum. Metapleuron rugose-pectinate; juxtacoxal carina indistinct; submetapleural carina complete, strong. Pleural carina of propodeum strong; propodeal spiracle oval, separated from pleural carina by ca 0.5–0.7× its length, connected to pleural carina by a weak ridge. Propodeum long, its apex reaching middle length of hind coxa, coarsely rugose-pectinate, area superomedia and area petiolaris with distinct transverse wrinkles and rugosity, medially not impressed. Area basalis trapezoidal, rather short, ca 0.5× as long as its basal width; area superomedia hexagonal, relatively short and moderately wide, ca 1.6× as long as wide, reaching up to basal 0.40–0.45× length of propodeum, apically opened, confluent with area petiolaris; area petiolaris moderately wide. Propodeal carinae complete; lateromedian longitudinal carinae distinctly angulate at costulae and convergent behind costulae. Fore wing with long-stalked areolet, its stalk 0.7–0.9 × as long as maximum height of areolet, 3rs-m present,
pigmented, second recurrent vein (2m-cu) close to
distal corner of areolet; distal abscissa of Rs
straight; nervulus (cu-a) interstitial to slightly
postfurcal, weakly inclivous; postnervulus (abscissa of Cu1 between 1m-cu and Cu1a + Cu1b)
intercepted slightly above its middle by Cu1a;
lower external angle of second discal cell acute.
Hind wing with nervellus (cu-a + abscissa of Cu1
between M and cu-a) broken, intercepted by
discoidea (distal abscissa of Cu1) at about
posterior 0.2–0.3× its length, strongly inclivous
above discoidea, weakly reclivous below
discoidea; discoidea spectral, proximally
connected to nervellus. Coxae granulate with
weak punctures. Hind femur relatively stout, ca
5× as long as high. Inner spur of hind tibia ca
0.5× as long as first tarsomere of hind tarsus.
Tarsal claws slightly longer than arolium, basal
two-third with strong pecten.

Metasoma. Metasoma with short, greyish to
light brownish hairs, compressed, petioli smooth,
from postpetioli finely granulate to
shagreened. First tergite ca 4.6–4.8× as long as
width of its apical margin, 1.1–1.2× as long as
second tergite, ca 0.95× as long as hind femur,
without glymma; dorsomedian carina of first ter-
gite missing; postpetioli bulging. Suture separat-
ing first tergite from first sternite situated little
above mid-height at basal third of first metasomal
segment. Second tergite long and slender, ca 1.8–
2.1× as long as its apical width; thyridium small,
oval, its distance from basal margin of tergite ca
3× as long as its length, not connected to basal
margin of tergite by a groove. Posterior margins
of apical tergites medially distinctly excised.
Ovipositor sheath 1.2–1.4× as long as hind tibia;
ovidpositor compressed, evenly, weakly upcurved.

Colour. Antenna dark brown, scapus and
pedicellus ventrally more or less extensively
orange brown. Head black except palpi and man-
dible yellow, mandibular teeth dark reddish
brown. Mesosoma black except tegula orange
brown. Metasoma: first tergite black, postpetioli
laterally and apically very dark reddish brown;
second tergite blackish, apical margin and
apicolateral corners narrowly reddish brown; third
tergite blackish to dark brown, subapically widely
reddish, apically narrowly dark brown, sometimes
less extensively reddish; following tergites re-
ddish with dark brown dorsal patches; ovipositor
sheath blackish. Wings hyaline, wing veins and
pterostigma brown. Fore leg: entirely reddish or-
range, apical tarsomere darkened. Middle leg:
coxa dark brown, apically narrowly orange
brown; rest of leg reddish orange, apical tarso-
mere darkened. Hind leg: coxa blackish, apically
very narrowly orange brown; rest of leg reddish
orange, except tibia dorsally and tarsus more or
less darkened, brownish, rarely trochanter partly
brownish.

Male. Similar to female in all characters de-
scribed above, except: propodeal spiracle elongate
oval, separated from pleural carina by ca about its
length, connected to pleural carina by a strong
ridge; propodeal carinae and sculpture stronger
than in female; stalk of areolet little shorter than
in female; first tergite slenderer, ca 5.5× as long
as width of its apical margin, 1.3× as long as
second tergite; third and following tergites short,
posterior margins medially not excised; claspers
narrowly, deeply notched dorsally; first tergite
entirely, second and third tergites almost entirely
black, dorsal patches of apical tergites larger and
darker than in female; wings subhyaline.

Distribution. South Africa.

Etymology. The specific epithet "aurantia" is the
feminine form of the Latin adjective "aurantius", -a,
-um meaning orange-coloured; it refers to the
colouration of legs of the new species.

Remarks. The new species is similar to Ventu-
ria canescens (Gravenhorst, 1829), which could
be distinguished from the new species by its
following characteristics: gena shorter (in dorsal
view ca 0.3× as long as eye width) and more
strongly narrowed behind eye, background of
mesopleuron somewhat smoother, more finely
sculptured, posterior transverse carina of meso-
sternum normal, area superomedia much more
elongate and narrow (ca 2× as long as wide),
lateromedian longitudinal carinae about parallel
and not distinctly angulate at costulae, areolet
Vas: New species and records of Venturia Schrottky, 1902

Figures 1–3. Venturia aurantia sp. nov. 1 = holotype, lateral habitus (scale bar = 1 mm); 2 = head, dorsal view; 3 = shape of median areas of propodeum.

short-stalked or subsessile, ovipositor sheath longer, ca 1.6× as long as hind tibia, male claspers more widely and less deeply notched dorsally, tegula yellow, fore and middle coxae, trochanters, trochantelli, and hind trochantellus yellowish, femora and tibiae mostly yellowish brown to brownish, not orange.

Venturia canescens (Gravenhorst, 1829)

Material examined. Three females and one male, Tanzania, Usa River, 1190m, 1965, leg. J. Szunyoghy, Id. No. HNHM-HYM 154976–154979. – The specimens are deposited in HNHM (Budapest).

Remarks. First record for Tanzania. This species has a worldwide distribution (Yu et al. 2012, Vas 2019a).

Venturia crassicaput (Morley, 1926)

Remarks. First records for South Africa. This species was described from Zimbabwe and recently reported from Tanzania (Yu et al. 2012, Vas 2019a).
**Venturia erythrina** sp. nov.

(Figures 4–6)

**Material examined.** Holotype: female, Africa or. [= orientalis], [Tanzania], Arusha, 1906, leg. [K.] Katona [= K. Kittenberger]; specimen pinned, Id. No. HNHM-HYM 154972. – The holotype specimen is deposited in HNHM (Budapest).

**Diagnosis.** Among the Afrotropical species of the genus, *Venturia erythrina* sp. nov. could be reliably identified by the combined presence of the following characters: gena long, in dorsal view 0.7× as long as eye width, subparallel behind eye, area superomedia moderately narrow, 1.6× as long as wide, ovipositor sheath 2.4× as long as hind tibia, ovipositor tip strongly upcurved, scapus ventrally brownish yellow, mandible yellowish except teeth, tegula light reddish brown, metasoma rusty reddish except basal 0.4 of first tergite black and extreme base of second tergite very narrowly blackish, all legs, including coxae, reddish to rusty reddish, except middle and hind tibiae dorsally brownish, basal 0.2 of hind tibia dark brown, middle and hind tarsi brown.

**Description.** Female (Figs 4–6). Body length **ca** 10 mm, fore wing length **ca** 7 mm.

**Head.** Antenna with 42 flagellomeres; first flagellomere **ca** 3× as long as wide apically; preapical flagellomeres longer than wide. Head transverse, matt, with dense, short, silvery hairs. Ocular-ocellar distance 0.9× as long as ocellus diameter, posterior ocellar distance 1.2× as long as ocellus diameter, posterior ocellar distance 1.3× as long as ocellar-ocellar distance. Inner eye orbits slightly indented, about parallel. Gena distinctly, densely punctate on granulate surface, moderately buccate, long, in dorsal view 0.7× as long as eye width, subparallel behind eye. Occipital carina complete, medially evenly arched, reaching hypostomal carina distinctly before base of mandible, hypostomal carina not elevated. Frons flat, without median longitudinal carina, rugose-punctate. Face almost flat in profile, densely rugose-punctate. Clypeus weakly rugose with dense punctures, very weakly separated from face, flat in profile, relatively wide, its apical margin almost straight, sharp. Malar space short, 0.4× as long as basal width of mandible. Mandible moderately long, lower margin of mandible with moderately wide flange from base toward teeth, flange gradually narrowed toward teeth, mandibular teeth of equal length.

**Mesosoma.** Mesosoma with dense, short, silvery hairs. Pronotum strongly and densely rugose-punctate, ventral half with weak transverse wrinkles; epomia distinct. Mesoscutum coarsely rugose-punctate, convex in profile, about as long as wide, notaulus not developed. Scuto-scutellar groove wide, deep. Scutellum rugose-punctate, convex, lateral carina indistinct. Upper half of mesopleuron moderately rugose with strong, dense punctures, lower half strongly, densely punctate on coarsely granulate background, distances between punctures smaller than puncture diameters, with weak transverse wrinkles anterior to speculum; speculum relatively small, very finely granulate to smooth, shiny; mesopleural suture impressed with short, relatively weak transverse costae. Epinomial carina complete, strong, pleural part bent to anterior margin of mesopleuron reaching it below its middle height, transversal part (i.e. part at the level of sternaulus running through the epicnemium to the ventral edge of pronotum) not developed, ventral part (behind fore coxae) complete, slightly elevated. Sernaulus indistinct. Posterior transverse carina of mesosternum complete, little elevated, medially not excised. Metanotum rugose-punctate, **ca** 0.5× as long as scutellum. Metapleural rugose-punctate; juxtacoxal carina indistinct; submetapleural carina complete, strong. Pleural carina of propodeum strong; propodeal spiracle elongate oval, separated from pleural carina by **ca** 0.5× its length, connected to pleural carina by a weak ridge. Propodeum long, its apex reaching middle length of hind coxa, coarsely and densely rugose-punctate, except area superomedia granulate with relatively weak transverse wrinkles and area petiolaris with mostly transverse rugosity, mediately not impressed. Area basalis trapezoidal, small, about as long as its basal width; area superomedia elongate hexagonal, moderately narrow, 1.6× as long as wide, reaching up to basal 0.35× length of propodeum, behind costulae.
Vas: New species and records of Venturia Schrottky, 1902

Figures 4–6. Venturia erythrina sp. nov. 1 = holotype, lateral habitus (scale bar = 1 mm); 2 = head, dorsal view; 3 = shape of median areas of propodeum.

distinctly constricted; area petiolaris moderately narrow. Propodeal carinae strongly developed, area superomedia apically opened, confluent with area petiolaris. Fore wing with short-stalked, relatively large areolet, its stalk about 0.25× as long as maximum height of areolet, 3rs-m present, pigmented, second recurrent vein (2m-cu) little to distal middle of areolet; distal abscissa of Rs almost straight, distally weakly curved toward wing margin; nervulus (cu-a) interstitial, strongly inclivous; postnervulus (abscissa of Cu1 between 1m-cu and Cu1a + Cu1b) intercepted slightly above its middle by Cu1a; lower external angle of second discal cell acute. Hind wing with nervellus (cu-a + abscissa of Cu1 between M and cu-a) weakly broken, intercepted by discoidella (distal abscissa of Cu1) at about posterior 0.3× its length, vertical above discoidella, weakly reclivous below discoidella; discoidella spectral, proximally connected to nervellus. Coxae granulate with distinct, dense punctures. Hind femur relatively stout, ca 5× as long as high. Inner spur of hind tibia ca 0.5× as long as first tarsomere of hind tarsus. Tarsal claws strong, distinctly longer than arolium, basal half with strong pecten.

Metasoma. Metasoma with short, greyish hairs, moderately compressed, petiolar smooth, from postpetiolar finely granulate to shagreened. First tergite ca 4× as long as width of its apical margin, 1.1× as long as second tergite, 0.95× as long as hind femur, without glymma; dorsomedian carina of first tergite missing; postpetiolar bulging. Suture separating first tergite from first sternite situated at about mid-height at basal third of first metasomal segment. Second tergite long and slender, ca 2× as long as its apical width; thyridium small, oval, weak, its distance from basal margin of tergite ca 3× as long as its length, not connected to basal margin of tergite by a groove. Posterior margins of third and following tergites medially distinctly, widely concave. Ovipositor sheath 2.4× as long as hind tibia; ovipositor compressed, shaft weakly, tip strongly upcurved.
**Colour.** Antenna dark brown, scapus ventrally brownish yellow. Head black except palpi and mandible yellowish, mandibular teeth dark brown. Mesosoma black except tegula light reddish brown. Metasoma rusty reddish except basal 0.4 of first tergite black and extreme base of second tergite very narrowly blackish; ovipositor sheath blackish. Wings weakly infuscate, wing veins and pterostigma brown. All legs, including coxae, reddish to rusty reddish, except middle and hind tibiae dorsally brownish, basal 0.2 of hind tibia dark brown, middle and hind tarsi brown.

**Male.** Unknown.

**Distribution.** Tanzania.

**Etymology.** The specific epithet *erythrina* is the feminine form of the Latinised Greek adjective *erythrus*, -a, -um meaning reddish; it refers to the colouration of legs and metasoma of the new species.

**Remarks.** The new species is most similar to *Venturia crassicaput* (Morley, 1926), which species could be easily distinguished from the new species by its almost entirely black middle and hind coxae, dorsally less darkened hind tibia, more extensively blackish basal tergites of metasoma, more elongate area superomedia (ca 2× as long as wide), and distinctly longer ovipositor sheath (almost 3× as long as hind tibia).

**Venturia ignea sp. nov.**

(Figures 7–9)

**Material examined.** Holotype: female, Ghana, Ashanti region, Kumasi, 293m, 4.II.1968, leg. S. Endrödy-Younga, light trap, No. 297; specimen card-mounted, Id. No. HNHM-HYM 154980. – Paratype: female, same locality, date, collector; antennae damaged, specimen card-mounted, Id. No. HNHM-HYM 154981. – The holotype and paratype specimens are deposited in HNHM (Budapest).

**Diagnosis.** Among the Afrotropical species of the genus, *Venturia ignea* sp. nov. could be reliably identified by the combined presence of the following characters: gena moderately long, in dorsal view 0.55× as long as eye width, weakly narrowed behind eye, area superomedia rather elongate and narrow, ca 3× as long as wide, with weak, mostly transverse rugosity, area petiolaris irregularly rugose-punctate without transverse wrinkles, propodeal carinae partly weakened, ovipositor sheath 1.3–1.4× as long as hind tibia, apical half of ovipositor evenly, strongly up-curved, scapus and pedicellus ventrally yellow, mandible yellow except teeth, tegula yellowish, metasoma amber-coloured except petiolus, basal half of second tergite and basal quarter of third tergite black to dark brown, fore and middle legs predominantly yellowish, base of coxae narrowly darkened, femora and ventral side of tibiae with light orange tinge, hind coxa almost entirely dark, trochanter, trochantellus and dorsal side of tibia yellowish, femur, ventral side of tibia and tarsus light orange.

**Description.** Female (Figs 7–9). Body length ca 8 mm, fore wing length ca 5 mm.

**Head.** Antenna with 45 flagellomeres; first flagellomere ca 3× as long as wide apically; preapical flagellomeres longer than wide. Head transverse, matt, with dense, relatively long, silvery hairs. Ocular-ocellar distance about as long as ocellus diameter, posterior ocellar distance 1.6–1.7× as long as ocellus diameter, posterior ocellar distance 1.6–1.7× as long as ocellar-ocellar distance. Inner eye orbits slightly indented, subparallel. Gena granulate with dense, superficial punctures, moderately long, in dorsal view 0.55× as long as eye width, weakly narrowed behind eye. Occipital carina complete, medially evenly arched, reaching hypostomal carina little before base of mandible, hypostomal carina not elevated. Frons flat, without median longitudinal carina, rugose-punctate. Face weakly convex in profile, rugose-punctate, punctures moderately strong. Clypeus rugose-punctate, very weakly separated from face, almost flat in profile, relatively wide, its apical margin sharp, medially straight, truncate, laterally very weakly convex. Malar space short, 0.4× as long as basal width of mandible. Mandible relatively long and strong, lower margin of mandible with a moderately wide flange from base toward teeth, flange gradually...
narrowed toward teeth, mandibular teeth of equal length.

**Mesosoma.** Mesosoma with dense, short, silvery hairs. Pronotum rugose-punctate, ventral third with weak, short transverse wrinkles; epomia weak. Mesoscutum rugose-punctate, convex in profile, 1.1× as long as wide, notaulus not developed. Scuto-scutellar groove wide, moderately deep. Scutellum rugose-punctate, convex, lateral carina indistinct. Upper half of mesopleuron weakly rugose with dense punctures, lower half densely punctate on granulate background, distances between punctures smaller than puncture diameters, with rather weak and short transverse wrinkles anterior to scutellum; scutellum very finely granulate, subpolished, ventrally smooth; mesopleural suture impressed with short, indistinct transverse costae. Epinemicarina carina complete, strong, pleural part bent to anterior margin of mesopleuron reaching it below its middle height, transversal part (i.e. part at the level of sernaulus running through the epinemicum to the ventral edge of pronotum) not developed, ventral part (behind fore coxae) complete, not elevated. Sernaulus indistinct. Posterior transverse carina of mesosternum complete. Metanotum rugose-punctate, ca 0.4× as long as scutellum. Metapleuron rugose-punctate; juxta-coxal carina indistinct; submetapleural carina complete, strong. Pleural carina of propodeum strong; propodeal spiracle elongate oval, almost touching pleural carina. Propodeum long, its apex reaching middle length of hind coxa, coarsely, irregularly rugose-punctate except area superomedia with weak, mostly transverse rugosity; area petiolaris irregularly rugose-punctate without transverse wrinkles or transverse rugosity, mediately not impressed. Area basalis triangular, narrower, longer than its basal width; area superomedia rather elongate and narrow, ca 3× as long as wide, reaching up to basal 0.5× length of propodeum, apically opened, confluent with area petiolaris; area petiolaris moderately narrow. Propodeal carinae partly weakened; lateromedian longitudinal carinae behind costulæ weak; lateral longitudinal carinae obsolescent. Fore wing with short-stalked, relatively large areolet, its stalk ca 0.4× as long as maximum height of areolet, 3rs-m present, pigmented, second recurrent vein (2m-cu) distinctly pigmented to middle of areolet; distal abscessa of Rs almost straight, distally weakly curved toward wing margin; nervulus (cu-a) interstitial, weakly inclivous; postnervulus (abscessa of Cu1 between 1m-cu and Cu1a + Cu1b) intercepted at about its middle by Cu1a; lower external angle of second discal cell weakly acute. Hind wing with nervellus (cu-a + abscessa of Cu1 between M and cu-a) broken, intercepted by discoidella (distal abscessa of Cu1) at about posterior 0.4× its length, vertical above discoidella, strongly reclinous below discoidella; discoidella spectral, proximally connected to nervellus. Coxae granulate with weak punctures. Hind femur stout, ca 4.6× as long as high. Inner spur of hind tibia ca 0.5× as long as first tarsomere of hind tarsus. Tarsal claws slightly longer than arolium, basal half with strong pecten.

**Metasoma.** Metasoma with short, whitish hairs, compressed, petioulis smooth, from post-petrioulis finely granulate to shagreened. First tergite ca 4.5–4.7× as long as its apical margin, 1.0–1.1× as long as second tergite, about as long as hind femur, without glymma; dorso-median carina of first tergite missing; postpetioulus bulging. Suture separating first tergite from first sternite situated little above mid-height at basal third of first metasomal segment. Second tergite long and slender, ca 2.2–2.4× as long as its apical width; thrytidium small, oval, its distance from basal margin of tergite ca 4× as long as its length, not connected to basal margin of tergite by a groove. Posterior margins of apical tergites medially slightly and widely excised. Ovipositor sheath 1.3–1.4× as long as hind tibia; ovipositor compressed, apical half evenly, strongly upcurved.

**Colour.** Antenna yellowish brown, dorsally brown, scapus and pedicellus ventrally yellow. Head black except palpi and mandible yellow, mandibular teeth dark brown. Mesosoma black except tegula yellowish. Metasoma amber-coloured except petioulus, basal half of second tergite and basal quarter of third tergite black to dark brown; ovipositor sheath dark brown. Wings hyaline, wing veins and pterostigima brown. Fore and middle legs: coxae pale yellow, basal third to
half brownish; trochanters and trochantellae pale yellow; femora and ventral side of tibiae yellowish with light orange tinge, dorsal side of tibiae and tarsi yellowish. Hind leg: coxa blackish to dark brown, apically narrowly yellowish; trochanter and trochantellus pale yellow; femur, ventral side of tibia and tarsus light orange, dorsal side of tibia yellowish.

**Male.** Unknown.

**Distribution.** Ghana.

**Etymology.** The specific epithet *ignea* is the feminine form of the Latin adjective *igneus, -a, -um* meaning fiery, inflamed, glowing; it refers to the colouration of metasoma and legs of the new species.

**Remarks.** The new species is somewhat similar to *Venturia jordanae* Fitton, 1994, which species could be readily distinguished from the new species by its buccate, distinctly longer gena (in dorsal view ca 0.9× as long as eye width), transversely striated area petiolaris and area superomedia, shorter and less upcurved ovipositor (ovipositor sheath as long as hind tibia), and distinctly darker coloured hind legs and metasoma.

**Venturia peringueyi** (Cameron, 1906)

**Figures 7–9. Venturia ignea** sp. nov. 1 = holotype, lateral habitus (scale bar = 1 mm); 2 = head, dorsal view; 3 = shape of median areas of propodeum.
First description of male sex. This species, as well as its junior synonym *Venturia areolata* (Cameron, 1926), was described from South Africa, based on female sex only (Cameron 1906). The male is similar to the female except in the following characters: antenna with 35–36 flagellomeres; gena little longer than in female, in dorsal view 0.55–0.60× as long as eye width, less strongly narrowed behind eye; mesopleuron more strongly punctate; propodeal carination and sculpture stronger; area superomedia and area petiolaris little narrower; claspers widely, moderately deeply notched dorsally; metasoma distinctly darker coloured than in female, petiulus dark brown, postpetiulus reddish brown, second and third tergites entirely, fourth tergite basally brownish with weak reddish brown tinge, following tergites dark brown.

*Venturia veruta* sp. nov.

(Figures 10–12)

Diagnosis. Among the Afrotropical species of the genus, *Venturia veruta* sp. nov. could be reliably identified by the combined presence of the following characters: gena moderately long, in dorsal view 0.55× as long as eye width, weakly narrowed behind eye, area superomedia elongate, narrow, ca 2× as long as wide, propodeal carinæ partly developed, partly obsolescent, ovipositor sheath 2.9× as long as hind tibia, ovipositor straight, its apex very weakly sinuous, scapus and pedicellus ventrally narrowly yellowish brown, mandible yellow except teeth, tegula pale yellow, metasoma light amber-coloured except petiulus blackish, postpetiulus basally yellowish brown, basal two-third of second tergite and extreme base of third tergite dark brown, fore and middle legs, except coxae, yellowish, middle and hind coxae almost entirely dark, hind femur and tibia brownish yellow, tibia dorsally brownish.

Description. Female (Figs 10–12). Body length ca 8 mm, fore wing length ca 5 mm.

Head. Antenna with 43 flagellomeres; first flagellomere ca 3× as long as wide apically; preapical flagellomeres little longer than wide. Head transverse, matt, with dense, relatively long, greyish hairs. Ocular-ocellar distance about as long as ocellus diameter, posterior ocellar distance 1.4× as long as ocellus diameter, posterior ocellar distance 1.4× as long as ocular-ocellar distance. Inner eye orbits slightly indented, subparallel. Gena granulate with weak punctures, moderately long, in dorsal view 0.55× as long as eye width, weakly narrowed behind eye. Occipital carina complete, medially evenly arched, reaching hypostomal carina little before base of mandible, hypostomal carina not elevated. Frons flat, without median longitudinal carina, rugose-punctate, punctures weaker than on face and clypeus. Face flat in profile, rugose-punctate, punctures moderately strong. Clypeus rugose-punctate, very weakly separated from face, flat in profile, relatively wide, its apical margin sharp, medially straight, truncate, laterally weakly convex. Malar space short, 0.5× as long as basal width of mandible. Mandible relatively long and strong, lower margin of mandible with a rather narrow flange from base toward teeth, flange gradually narrowed toward teeth, upper mandibular tooth little longer than lower tooth.

Mesosoma. Mesosoma with dense, moderately short, silvery hairs. Pronotum rugose-punctate, ventral half with weak transverse wrinkles; epomia weak. Mesoscutum rugose-punctate, convex in profile, little longer than wide, notaulus not developed. Scuto-scutellar groove wide, relatively shallow. Scutellum rugose-punctate, convex, lateral carina indistinct. Upper half of mesopleuron moderately rugose with dense punctures, lower half densely punctate on coarsely granulate background, distances between punctures smaller than puncture diameters, with rather weak transverse wrinkles anterior to speculum; speculum relatively small, very finely granulate, subpolished; mesopleural suture impressed with short, weak transverse costae. Epinomial carina complete, strong, pleural part bent to anterior margin of mesopleuron reaching it below its middle height,
transversal part (i.e. part at the level of sternaulus running through the epicnemium to the ventral edge of pronotum) not developed, ventral part (behind fore coxae) complete, not elevated. Sternaulus indistinct. Posterior transverse carina of mesoscutum complete, slightly elevated, medi ally not excised. Metanotum rugose-punctate, ca 0.5× as long as scutellum. Metapleuron granulate to rugose with dense punctures; juxtacoxal carina indistinct; submetapleural carina complete, strong. Pleural carina of propodeum moderately strong; propodeal spiracle oval, separated from pleural carina by ca 0.5× its length. Propodeum long, its apex reaching little beyond middle length of hind coxa, coarsely rugose-punctate except area super omedia granulate with weak transverse wrinkles and area petiolaris granulate to rugose with re latively weak transverse wrinkles, medi ally not impressed. Area basalis triangular, small, about as long as its basal width; area supero media elongate, narrow, ca 2× as long as wide, reaching almost up to basal 0.5× length of propodeum, apically opened, confluent with area petiolaris; area petiolaris narrow. Propodeal carinae partly developed; lateromedian longitudinal carinae de veloped before costulae but relatively weak, be hind costulae obsolescent; costulae developed but relatively weak; lateral longitudinal carinae obsoles cent; posterior transverse carina only laterally developed. Fore wing with short-stalked, rela tively large areolet, its stalk ca 0.4× as long as maximum height of areolet, 3rs-m present, pigmented, second recurrent vein (2m-cu) little distal to middle of areolet; distal abscissa of Rs almost straight, distally weakly curved toward wing margin; nervulus (cu-a) interstitial, distinc tly incisive; postnervulus (abscissa of Cu1 between 1m-cu and Cu1a + Cu1b) intercepted slightly below its middle by Cu1a; lower external angle of second discal cell acute. Hind wing with nervellus (cu-a + abscissa of Cu1 between M and cu-a) broken, intercepted by discoidella (distal abscissa of Cu1) at about posterior 0.25× its length, vertical above discoidella; recli vious below discoidella; discoidella spectral, proximally connected to nervellus. Coxae granulate with weak punctures. Hind femur relatively stout, ca 5× as long as high. Inner spur of hind tibia ca 0.5× as long as first tarsomere of hind tarsus. Tarsal claws little longer than ariol, basal half with distinct pecten.

Metasoma. Metasoma with moderately short, whitish hairs, compressed, petiolar smooth, from postpetiolar finely granulate to shagreened. First tergite ca 5× as long as width of its apical margin, 0.9× as long as second tergite, as long as hind femur, without glymma; dorsomedian carina of first tergite missing; postpetiolar bulging. Suture separating first tergite from first sternite situated slightly above mid-height at basal third of first metasomal segment. Second tergite rather long and slender, ca 2.7× as long as its apical width; thyridium small, rather weak, subcircular, its distance from basal margin of tergite ca 3.5× as long as its length, not connected to basal margin of tergite by a groove. Posterior margins of third and following tergites medi ally slightly and widely concave, apical tergites more strongly excised medially. Ovipositor sheath 2.9× as long as hind tibia; ovipositor compressed, straight, its apex very weakly sinuous, dorsal preapical notch weak, indistinct.

Colour. Antenna brown, scapus and pedicellus ventrally narrowly yellowish brown. Head black except palpi and mandible yellow, mandibular teeth dark brown. Mesosoma black except tegula pale yellow. Metasoma light amber-coloured except petiolar blackish, postpetiolar basally yellowish brown, basal two-third of second tergite and extreme base of third tergite dark brown; ovi positor sheath blackish. Wings subhyaline, wing veins and pterostigma brown. Fore leg: coxa bas ally brownish, apically yellowish; trochanter, trochantellus, femur, tibia and tarsus yellowish. Middle leg: coxa dark brown, apically narrowly yellowish; trochanter, trochantellus, femur, tibia and tarsus yellowish, apical tarsomere brownish. Hind leg: coxa blackish to dark brown, apically very narrowly yellowish; trochanter brownish, apically yellowish; trochantellus yellowish; femur brownish yellow; tibia brownish yellow, dorsally brownish; tarsus brownish.

Male. Unknown.

Distribution. Uganda.
Etymology. The specific epithet *veruta* is the feminine form of the Latin adjective *verutus, -a, -um* meaning armed with a javelin; it refers to the long and straight ovipositor of the new species.

Remarks. The new species has a rather unique character combination, which is dissimilar to any known *Venturia* species in the region (see Diagnosis section). Due to the very long ovipositor it is rather superficially similar to *Venturia crassi-caput* (Morley, 1926), which species could be readily distinguished from the new species by its buccate, distinctly longer gena (in dorsal view ca 0.7× as long as eye width), stronger propodeal carination, strongly upcurved ovipositor tip, and predominantly reddish colouration of legs and metasoma.

ORIENTAL REGION

Before this study, 35 valid species were known from the region (Yu et al. 2012). Gupta & Maheshwary (1977) revised the Oriental species; since then only four species were described from the region (Kusigemati 1988, Sudheer & Narendran 2006). With the new species described below, the number of Oriental *Venturia* species increased to 36.

*Venturia biroi* sp. nov.

(Figures 13–15)

Material examined. Holotype: female, India or. [= orientalis], [Maharashtra state], Matheran, 10.VII.1902, leg. [L.] Bíró; specimen pinned, Id. No. HNHM-HYM 154967. – The holotype specimen is deposited in HNHM (Budapest).

Diagnosis. Among the Oriental species of the genus, *Venturia biroi* sp. nov. could be reliably identified by the combined presence of the following characters: antennal flagellomeres dark brown, scapus and pedicellus almost entirely pale yellow except a narrow brown stripe laterally,
frons without median longitudinal carina, face rugose-punctate, posterior ocellar distance 2.5× as long as ocellar-ocellar distance, mandible pale yellow, its lower margin with rather wide flange, gradually narrowed toward teeth, tegula pale yellow, mesopleuron and metapleuron strongly, densely punctate on smooth background, area superomedia elongate hexagonal, moderately narrow, 1.6× as long as wide, almost entirely smooth, area petiolaris with strong transverse wrinkles, fore wing with petiolate, long-stalked, small areolet, nervellus intercepted, ovipositor sheath 1.5× as long as hind tibia, first tergite black, apically brownish, second and third tergites blackish, apically narrowly reddish brown, following tergites dorsally blackish, laterally reddish brown, hind femur reddish brown, hind tibia reddish brown, subbasally and apically darkened, basal yellowish brown spot present but indistinct.

**Description.** Female (Figs 13–15). Body length ca 7 mm, fore wing length ca 4 mm.

**Head.** Antenna with 33 flagellomeres; first flagellomere long and slender, ca 4× as long as wide apically; preapical flagellomeres quadrate to slightly longer than wide. Head transverse, matt, with dense, greyish hairs. Ocular-ocellar distance 0.6× as long as ocellus diameter, posterior ocellar distance 1.5× as long as ocellus diameter, posterior ocellar distance 2.5× as long as ocellar-ocellar distance. Inner eye orbits slightly indented, parallel. Gena granulate with weak punctures, short, in dorsal view 0.3× as long as eye width, strongly narrowed behind eye. Occipital carina complete, medially evenly arched, reaching hypostomal carina little before base of mandible, hypostomal carina little elevated. Frons flat, without median longitudinal carina, rugose-punctate, punctures weaker than on face and clypeus. Face weakly convex in profile, strongly rugose-punctate. Clypeus strongly rugose-punctate, very weakly separated from face, almost flat in profile, relatively wide, its apical margin weakly convex, sharp. Malar space short, 0.4× as long as basal width of mandible. Mandible relatively long, lower margin of mandible with rather wide flange from base toward teeth, flange gradually narrowed toward teeth, mandibular teeth of equal length.

**Mesosoma.** Mesosoma with dense, short, greyish hairs. Dorsal third of pronotum rugose-punctate, ventral two-third smooth with strong transverse wrinkles; epomia weak. Mesocutum coarsely rugose-punctate, convex in profile, about as long as wide, notaulus not developed. Scutocutellar groove wide, relatively shallow. Scutellum punctate, apically rugose-punctate, convex, lateral carina indistinct. Mesopleuron strongly, densely punctate on smooth, shiny background, distances between punctures smaller than puncture diameters, with relatively long and strong transverse wrinkles anterior to speculum; speculum large, smooth, shiny; mesopleural suture impressed with short, weak transverse costae. Epinemiial carina complete, strong, pleural part bent to anterior margin of mesopleuron reaching it below its middle height, transversal part (i.e. part at the level of sternaulus running through the epinemiium to the ventral edge of pronotum) not developed, ventral part (behind fore coxae) complete, slightly elevated. Sternaulus indistinct. Posterior transverse carina of mesosternum complete, little elevated, medially not excised. Metanotum rugose-punctate, ca 0.4× as long as scutellum. Metapleuron strongly, densely punctate on smooth background; juxtacoxal carina indistinct; submetapleural carina complete, strong. Pleural carina of propodeum strong; propodeal spiracle elongate oval, separated from pleural carina by about its length, connected to pleural carina by a distinct ridge. Propodeum long, its apex reaching middle length of hind coxa, coarsely rugose-punctate except area superomedia almost entirely smooth and area petiolaris with strong transverse wrinkles, medially not impressed. Area basalis trapezoidal, shorter than its basal width; area superomedia elongate hexagonal, moderately narrow, 1.6× as long as wide, reaching up to basal 0.3× length of propodeum; area petiolaris moderately wide. Propodeal carinae strongly developed, area superomedia apically opened, confluent with area petiolaris. Fore wing with petiolate, long-stalked, small areolet, its stalk about as long as maximum height of areolet, 3rs-m present, pigmented, second recurrent vein (2m-cu) very
close to distal corner of areolet; distal abscissa of Rs straight; nervulus (cu-a) interstitial; postnervulus (abscissa of Cu1 between 1m-cu and Cu1a + Cu1b) intercepted little above its middle by Cu1a; lower external angle of second discal cell acute. Hind wing with nervulus (cu-a + abscissa of Cu1 between M and cu-a) broken, intercepted by discoidella (distal abscissa of Cu1) at about posterior 0.35× its length, vertical above discoidella, weakly reclivous below discoidella; discoidella spectral, proximally connected to nervulus. Coxae granulate with distinct punctures. Hind femur relatively stout, ca 5× as long as high. Inner spur of hind tibia ca 0.5× as long as first tarsomere of hind tarsus. Tarsal claws thin, little longer than arolium, basal half with small but distinct pecten.

Metasoma. Metasoma with short, greyish hairs, compressed, petiolar smooth, from postpetiolar finely granulate to shagreened. First tergite ca 4.2× as long as width of its apical margin, 1.15× as long as second tergite, 0.95× as long as hind femur, without glymma; dorsomedian carina of first tergite missing; postpetiolar bulging. Surface separating first tergite from first sternite situated little above mid-height at basal third of first metasomal segment. Second tergite long and slender, ca 2.3× as long as its apical width; thyridium small, oval, its distance from basal margin of tergite ca 3× as long as its length, connected to basal margin of tergite by a weak, almost indiscernibly shallow groove. Posterior margins of third and following tergites mediately slightly and widely concave. Ovipositor sheath 1.5× as long as hind tibia and 1.9× as long as hind femur (total length of exposed ovipositor 1.8× as long as hind tibia and 2.2× as long as hind femur); ovipositor compressed, weakly upcurved.

Colour. Antennal flagellomes dark brown, scapus and pedicellus almost entirely pale yellow except a narrow brown stripe laterally. Head black except palpi and mandible pale yellow, mandibular teeth reddish brown. Mesosoma black except tegula pale yellow. Metasoma: petiolar black, postpetiolar black, apically brownish; second and third tergites blackish, apically narrowly reddish brown; following tergites dorsally blackish, laterally reddish brown; ovipositor sheath blackish. Wings hyaline, wing veins and pterostigma brown. Fore leg: coxa dark brown, apical third yellowish; trochanter and trochantellus pale yellow; femur, tibia and tarsus yellowish brown, apical tarsomere brownish. Middle leg: coxa blackish to dark brown, apically narrowly yellowish; trochanter and trochantellus pale yellow; femur, tibia and tarsus yellowish brown, apical tarsomere brownish. Hind leg: coxa black, apically narrowly yellowish; trochanter and trochantellus pale yellow; femur reddish brown; tibia reddish brown, subbasally and apically darkened, basal yellowish brown spot present but rather indistinct; tarsus brown except extreme base of first tarsomere very narrowly yellowish brown.

Male. Unknown.

Distribution. India.

Etymology. This species is dedicated to the memory of its collector, Lajos Biró (1856–1931), in honour of his exceedingly remarkable collecting activity and work for the Hungarian natural history collection, and especially for the Hymenoptera Collection.

Remarks. By using the identification key in Gupta & Maheshwary (1977), the new species key out with Venturia palmaris (Wilkinson, 1928) at couplet 14, but without complete match to the characters given in the couplet. Venturia palmaris (Wilkinson, 1928) could be distinguished from the new species by its following characteristics: posterior ocellar distance 1.8× as long as ocular-ocellar distance, frons with median longitudinal carina, area superomedical with weak transverse striae, total length of exposed ovipositor significantly longer (3× as long as hind femur), scapus and pedicellus only ventrally yellowish. The new species is also somewhat similar to Venturia girishi Sudheer et Narendran, 2006, which species could be easily distinguished from the new species by its not intercepted nervellus and distinctly shorter ovipositor sheath (1.6× as long as hind femur), and colouration differences of scapus, pedicellus, legs and metasoma. Venturia canescens (Gravenhorst, 1829) could also be readily distinguished from the new species by its large,
Vas: New species and records of *Venturia* Schrottky, 1902

Figures 13–15. *Venturia biroi* sp. nov. 1 = holotype, lateral habitus (scale bar = 1 mm); 2 = head, dorsal view; 3 = shape of median areas of propodeum.

sessile or sub sessile areolet, significantly longer, narrower and more strongly sculptured area superomedia, and colouration differences of scapus, pedicellus, legs and metasoma.

**PALAEARCTIC REGION**

Eight valid species are known from the region (Yu et al. 2012). An identification key to the Western Palaearctic species was given by Vas (2019a).

*Venturia canescens* (Gravenhorst, 1829)

*Material examined*. Two females, Cyprus, Larnaka, VI.1900, leg. Glaszner, Id. No. HNHM-HYM 154962, 154963. – One female, [Greece], Crete [= Crete], Heraklion [= Heraklion], V.1906, leg. [L.] Bíró, Id. No. MZLU-HYM 154961. – The specimens are deposited in HNHM (Budapest).

**Remarks**. First records for Cyprus and Crete. This species has a worldwide distribution (Yu et al. 2012, Vas 2019a).

**Acknowledgements** – I am grateful to Rune Bygebjerg (Biological Museum, Lund) for the opportunity to borrow and study unidentified specimens from the collection of Biological Museum, Lund University. I thank Marin Husemann (Zoological Museum, Hamburg) for his efforts in locating relevant type material. The author was supported by the Hungarian Government, Ministry of Human Capacities (Emberi Erőforrások Minisztériuma) in the frame of the NTP-NFTÖ-19-B-0007 scholarship (Nemzet Fiatal Tehetségeiért Ösztöndíj).
